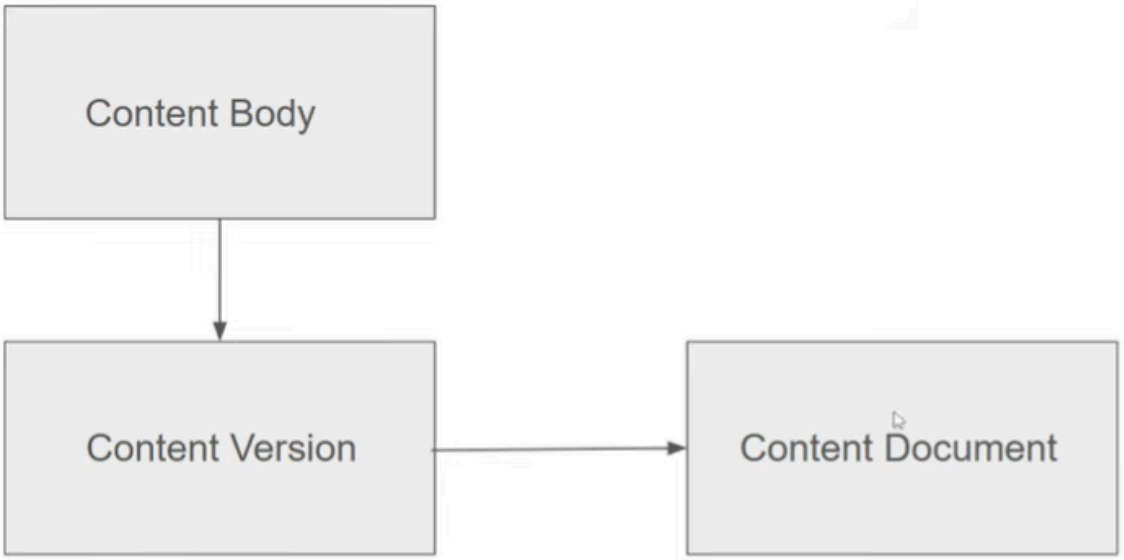
File Object Relationships

Content Version represents a specific version of a document in Salesforce CRM content or Salesforce Files ,it store the content version of the file when it get created every time a new version is created

After the content version immediately content body and content document is created,If you are trying to query the `ContentDocument` to find the file body, you will fail. The `ContentDocument` record is just a shell—it holds the metadata (who owns it, when it was deleted). It does not hold the file data.

To get the file content, you must query the content version

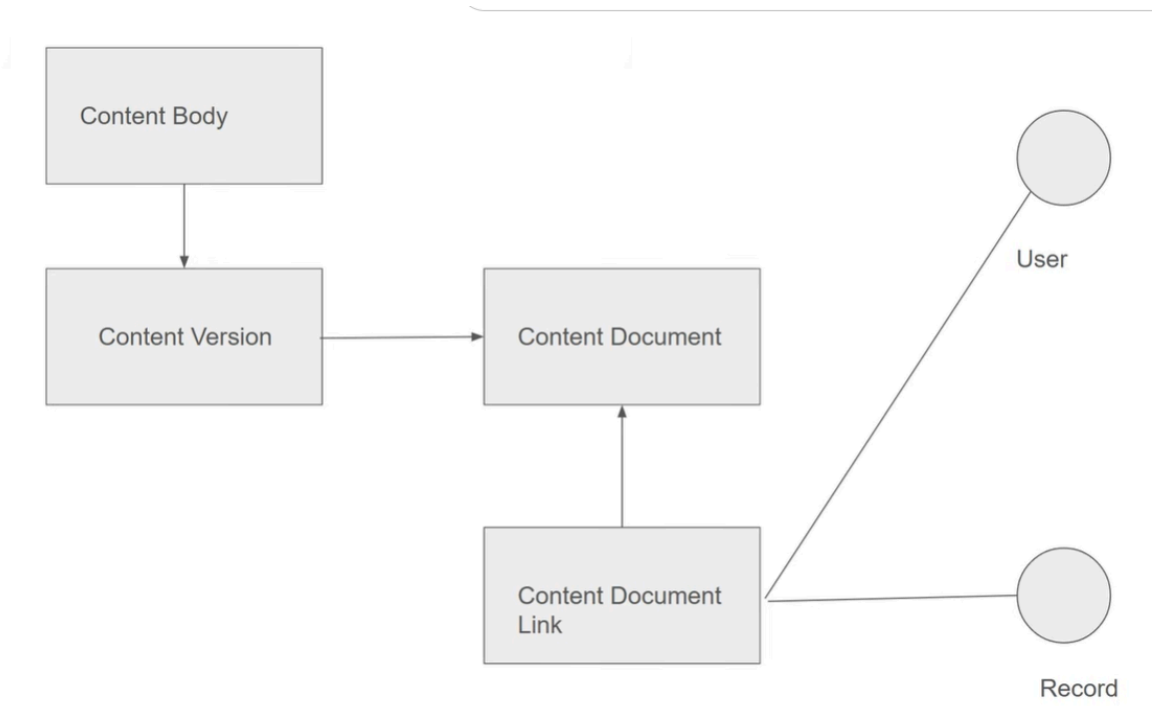
Here the arrow head represent the parent and tail represent the child



Whenever we are uploading a file from a record that link should be linked with the record and for that reason an object called as content document or the record of the object as content document link will get created ,its job is to connect the user with the record via content document link

When you upload a file to a record, Salesforce performs a multi-step process to ensure the file is both stored and shared correctly:

1. **The Data (ContentVersion):** First, a ContentVersion record is created. This holds the actual file data (the "blob"), the title, and the file extension.
2. **The Parent (ContentDocument):** Upon creating the version, Salesforce automatically generates a ContentDocument. This is the "container" or "parent" record that stays the same even if you upload newer versions of the file later.
3. **The Bridge (ContentDocumentLink):** To make the file "visible" on the record, a `ContentDocumentLink` record is created. Its specific job is to link the ContentDocument to a LinkedEntityId (which is the ID of the Account, Case, or Lead).
4. **The Visibility:** Importantly, the link doesn't just connect the file to the record; it also usually creates a second link between the file and the User who uploaded it. This ensures the file appears in the record's "Files" related list *and* in the user's personal file library.



- When a file is uploaded, it is stored as a ContentDocument (parent record).
- Each version of that file is a ContentVersion.
- By default, the file is not publicly accessible.

Now, when we want to share the file via a public URL:

- Salesforce creates a ContentDistribution record.
- This record acts as the public sharing link.
- It connects (junction-like behavior) to the ContentVersion (not directly to ContentDocument).
